ABSTRACT

This tutorial will present the highlights of the SIMSCRIPT II. 5 approach to building discrete event simulation models. The approach will be to construct a small example problem, implement the program in SIMSCRIPT II.5, and then to display the modularity which is possible with SIMSCRIPT II.5 by adding several "real-world" complexities to the model.

1. BACKGROUND

Simulation languages are (or should be) more than extensions of general-purpose programming languages designed to ease the burden of programming simulation problems. The influence of a good simulation language should be felt during the specification and model design stages of simulation as well as during computer implementation. If the "world-view" of the simulation language is well understood, and if the world-view is appropriate for a given problem, then the language should aid immeasurably in reducing the effort (and consequently elapsed time) in transforming model from concept to realization.

2. SIMSCRIPT II.5 WORLD-VIEW

SIMSCRIPT is a discrete-event language. Actions are modelled in terms of events. Sequences of events describing actions of a single object (or entity) are modelled as processes. Many important relationships are described dynamically in terms of entities-attributes-sets. This very powerful data structuring is one of the unique features of the language. The implementation in SIMSCRIPT of the classical simulation problems, such as small queueing models or job-shop simulations, have been described elsewhere (see References).

3. SIMSCRIPT II.5 IMPLEMENTATIONS

SIMSCRIPT II.5 has been implemented on seven different manufacturer's computers including IBM, HONEYWELL, CDC, Sperry, VAX, NCR, PRIME, Gould and VAX/UNIX and most recently the IBM PC. Development is underway for Data General. A major emphasis is to achieve portability of models from one machine to another since the type of models typically written in SIMSCRIPT have a fairly long lifetime and are often shared among a community of users with different computers.

4. SIMSCRIPT II.5 AVAILABILITY

SIMSCRIPT II.5 is the proprietary product of CACI and is available from them for lease or purchase.

A university program is supported by CACI in which SIMSCRIPT is supplied to educational institutions for the cost of distribution.

5. THE TUTORIAL EXAMPLE

The tutorial is built around a simple queueing problem first presented in (SCHRIBER) and later revised in (FISHMAN 1978). An African Port consists of three docks serviced by a single tug. Ships which arrive to be loaded must use the tug to enter and leave the docks. The ships arrive according to an exponential distribution of inter-arrival times with a mean of eleven hours. The ships are of three sizes distributed as follows:

25% have a mean loading time of 18 hours
55% have a mean loading time of 24 hours
20% have a mean loading time of 36 hours

The times are all exponentially distributed about these means. The time for moving a ship into or out of a dock is also exponentially distributed with a mean of one hour. Ships queue for the tug and/or the dock on a first-come-first-serve basis.

The first task is to model this existing situation and measure the utilization factors for the tug and the dock. In addition, the congestion in the harbor (queueing statistics for the tug and dock) are to be measured. Finally, statistics on the inport time for the ships should be collected.

After this simple model is developed, the next phase is to superimpose a new category of tanker. These new tankers belong to a fixed size fleet. They have a mean loading time of 21 hours and require the same tug and dock services as the other tankers. When they leave the port, they make a round-trip to their destination in a mean time of ten days (again exponentially distributed). The same statistics should be reported as above in order to determine the impact of the new tankers on the port.

The next complication to be added to the model is the effect of external interruptions such as storms and smog. A storm serves to delay the arrival of ships and to detain them when ready to depart. Smog alerts cause the unloading of ships to be interrupted until the smog alert is lifted. Since storms and smog are fairly rare occurences, these phenomena are to be represented as they actually occurred over some historical period.

Finally, in order to verify the correct execution of the model, the SIMSCRIPT tools for debugging will be added to the model. In particular the animation capabilities of PC SIMSCRIPT will be used to illustrate an anomaly in the model performance which might not otherwise have been detected. A discussion of the proper use of animation in the simulation environment and the very powerful capabilities of SIMANIMATION will follow.

EDWARD C. RUSSELL

Edward C. Russell is Vice President of CACI and manager of the Modelling and Simulation Department Group. He has responsibility for the development and distribution of CACI Software Products including SIMSCRIPT II.5, NETWORK II.5, and SIMFACTORY. He has developed and regularly teaches a one-week short course on Simulation and SIMSCRIPT II.5 . He is also actively engaged in major modelling and simulation projects. He is the author of the teaching text for SIMSCRIPT , Building Simulation Models with SIMSCRIPT II.5 (CACI, 1983).

Dr. Russell's academic background includes a BSEE from Wayne State University and MSE and PhD degrees in computer science from the University of California at Los Angeles (UCLA).
